Important features of the protein:**Signal peptide:**

amino acids 1-42

Transmembrane domains:

amino acids 19-42, 61-83, 92-114, 209-230,

N-glycosylation site.

amino acids 134-138

Tyrosine kinase phosphorylation site.

amino acids 160-168, 160-169

N-myristoylation site.

amino acids 75-81, 78-84, 210-216, 214-220, 226-232

Prokaryotic membrane lipoprotein lipid attachment site.

amino acids 69-80, 211-222

1990-1991 "1990-1991"

Signal peptide:

amino acids 1-29

Transmembrane domain:

amino acids 9-31 (type II)

N-glycosylation site.

amino acids 64-68, 115-119

cAMP- and cGMP-dependent protein kinase phosphorylation site.

amino acids 50-54

Casein kinase II phosphorylation site.

amino acids 3-7, 29-33, 53-57, 197-201

Tyrosine kinase phosphorylation site.

amino acids 253-262

N-myristoylation site.

amino acids 37-43, 114-120, 290-294

Important features:**Signal peptide:**

amino acids 1-16

Transmembrane domains:

amino acids 317-341, 451-470, 481-500, 510-527, 538-555, 831-850,
 1016-1034, 1052-1070

Leucine zipper pattern.

amino acids 843-864

N-glycosylation sites.

amino acids 37-40, 268-271

FIGURE 61

VCASVQEGGKDSCQGDGGPLVCNQSLQGIISWGQDPCAITRKPGVYTKVCKYVDWIQETMKNN

Important features:**Signal peptide:**

amino acids 1-18

Serine proteases, trypsin family, histidine active site.

amino acids 58-63

N-glycosylation sites.

amino acids 99-102, 165-168, 181-184, 210-213

Glycosaminoglycan attachment site.

amino acids 145-148

Kringle domain proteins.

amino acids 197-209, 47-64

Serine proteases, trypsin family, histidine protein

amino acids 199-209, 47-63, 220-243

Apple domain proteins

amino acids 222-249, 189-222

KSYQDAVLEDIFKKNDHDGDGFI SPKEYNVYQHDEL

Important features:

Endoplasmic reticulum targeting sequence.

amino acids 219-222

N-glycosylation site.

amino acids 45-48

FKBP-type peptidyl-prolyl cis-trans isomerase

amino acids 87-223, 129-142

EF-hand calcium-binding domain proteins

amino acids 202-214, 195-214

Important features of the protein:

Signal peptide:

amino acids 1-36

N-glycosylation sites.

amino acids 139-142, 607-610, 724-727

Tyrosine kinase phosphorylation site.

amino acids 571-576

Gram-positive cocci surface proteins 'anchoring' hexapeptide.

amino acids 32-37

Important features of the protein:

Signal peptide:

amino acids 1-48

N-glycosylation site.

amino acids 68-71

Glycosaminoglycan attachment site

amino acids 188-191, 772-775

cAMP- and cGMP-dependent protein kinase phosphorylation site.

amino acids 182-185

Tyrosine kinase phosphorylation site.

amino acids 730-736

N-myristoylation sites.

amino acids 5-10, 19-24, 121-126, 125-130, 130-135, 147-152, 167-
172, 168-173, 174-179, 323-328, 352-357, 539-544, 555-560, 577-
582, 679-684, 682-687, 763-768

Amidation sites.

amino acids 560-563, 834-837

Leucine zipper pattern.

amino acids 17-38, 24-45

Neutral zinc metallopeptidases, zinc-binding region signature.

amino acids 358-367

10007494 "120601

Important features of the protein:**Signal peptide:**

amino acids 1-40

Transmembrane domain:

amino acids 25-47 (type II)

N-glycosylation sites.

amino acids 94-97, 180-183

Glycosaminoglycan attachment sites.

amino acids 92-95, 70-73, 85-88, 133-136, 148-151, 192-195, 239-242

N-myristoylation sites.

amino acids 33-38, 95-100, 116-121, 215-220, 272-277

Microbodies C-terminal targeting signal.

amino acids 315-317

Cytochrome c family heme-binding site signature.

amino acids 9-14

Important features of the protein:**Signal peptide:**

amino acids 1-19

Transmembrane domain:

amino acids 91-110

Glycosaminoglycan attachment site.

amino acids 44-47

cAMP- and cGMP-dependent protein kinase phosphorylation site.

amino acids 116-119

N-myristoylation site.

amino acids 91-96

FIGURE 207

Important features of the protein:**Signal peptide:**

amino acids 1-17

Transmembrane domain:

amino acids 1-24

N-glycosylation site.

amino acids 86-89

N-myristoylation sites.

amino acids 20-25, 45-50

Phospholipase A2 histidine active site.

amino acids 63-70

Figure 1. Schematic representation of the experimental design. The subjects were divided into two groups: the control group (CG) and the experimental group (EG). The CG was divided into two subgroups: the control group (CG) and the control group (CG). The EG was divided into two subgroups: the experimental group (EG) and the experimental group (EG). [illegible]

Figure 6 shows the effect of the concentration of the monomer on the polymerization rate. The rate increases with increasing monomer concentration, and the increase becomes more pronounced at higher concentrations. This is due to the fact that the rate of polymerization is proportional to the square root of the monomer concentration.

The effect of the concentration of the initiator on the polymerization rate is shown in Figure 7. The rate decreases as the initiator concentration increases, which is characteristic of free-radical polymerization. This is because the rate of termination increases with increasing initiator concentration, leading to a decrease in the overall rate of polymerization.

The effect of temperature on the polymerization rate is shown in Figure 8. The rate increases exponentially with increasing temperature, indicating that the reaction is highly sensitive to temperature changes. This is typical for many chemical reactions, where the rate constant increases significantly with temperature.

The effect of the solvent on the polymerization rate is shown in Figure 9. The rate is highest in benzene and lowest in chloroform, suggesting that the solvent plays a role in the mechanism of the reaction. Benzene may act as a better solvent for the radical species involved in the reaction, while chloroform may inhibit the reaction in some way.

The effect of the type of monomer on the polymerization rate is shown in Figure 10. The rate is highest for styrene and lowest for methyl methacrylate, indicating that the structure of the monomer affects the rate of polymerization. Styrene has a conjugated system that may facilitate the formation of a stable radical intermediate, while methyl methacrylate has a bulky ester group that may hinder the approach of the radical species.

The effect of the type of initiator on the polymerization rate is shown in Figure 11. The rate is highest for azobisisobutyronitrile (AIBN) and lowest for potassium persulfate (KPS), suggesting that the nature of the initiator also influences the reaction rate. AIBN is a thermal initiator that decomposes to form radicals, while KPS is an oxidative initiator that requires an external oxidant to generate radicals.

The effect of the pH of the solution on the polymerization rate is shown in Figure 12. The rate is highest at neutral pH and decreases at both low and high pH values. This suggests that the reaction is most favorable under neutral conditions, possibly due to the presence of certain functional groups or species that are active at that pH range.

The effect of the stirring speed on the polymerization rate is shown in Figure 13. The rate increases slightly with increasing stirring speed, but the effect is not very pronounced. This indicates that mass transfer is not the primary factor controlling the reaction rate in this system.

The effect of the reaction time on the polymerization rate is shown in Figure 14. The rate decreases over time, which is expected for a reaction that follows first-order kinetics. As the reaction progresses, the concentration of the reactants decreases, leading to a slower rate of polymerization.

The effect of the molecular weight of the monomer on the polymerization rate is shown in Figure 15. The rate is highest for the lowest molecular weight monomer and decreases as the molecular weight increases. This is likely due to the fact that smaller molecules diffuse more easily through the reaction medium, leading to a faster rate of polymerization.

The effect of the degree of substitution on the polymerization rate is shown in Figure 16. The rate is highest for the monomer with the highest degree of substitution and decreases as the degree of substitution decreases. This suggests that the substituents on the monomer play a significant role in determining the reactivity of the double bond towards the radical species.

The effect of the chain length of the monomer on the polymerization rate is shown in Figure 17. The rate is highest for the shortest chain length monomer and decreases as the chain length increases. This is similar to the trend observed for molecular weight, where smaller molecules generally react faster than larger ones.

The effect of the branching of the monomer on the polymerization rate is shown in Figure 18. The rate is highest for the branched monomer and lowest for the linear monomer, indicating that branching can enhance the reactivity of the monomer. Branching may lead to a more strained double bond or a more accessible radical center.

The effect of the steric hindrance of the monomer on the polymerization rate is shown in Figure 19. The rate is highest for the least sterically hindered monomer and decreases as steric hindrance increases. Steric hindrance can physically block the approach of the radical species to the double bond, slowing down the reaction.

The effect of the electronic effects of the monomer on the polymerization rate is shown in Figure 20. The rate is highest for electron-deficient monomers and lowest for electron-rich monomers. Electron-deficient monomers have a lower energy LUMO orbital, making them more susceptible to nucleophilic attack by the radical species.

The effect of the resonance stabilization of the monomer on the polymerization rate is shown in Figure 21. The rate is highest for monomers that lack resonance stabilization and lowest for those that have it. Resonance stabilization lowers the energy of the ground state of the monomer, making it less reactive towards the radical species.

The effect of the hydrogen bonding capability of the monomer on the polymerization rate is shown in Figure 22. The rate is highest for monomers that cannot form hydrogen bonds and lowest for those that can. Hydrogen bonding can stabilize the monomer and/or the transition state, affecting the overall energy profile of the reaction.

The effect of the solubility of the monomer in the reaction medium on the polymerization rate is shown in Figure 23. The rate is highest for monomers that are highly soluble and lowest for those that are poorly soluble. Solubility ensures that the monomer is available to participate in the reaction throughout the entire volume of the solution.

The effect of the viscosity of the reaction medium on the polymerization rate is shown in Figure 24. The rate decreases as the viscosity of the medium increases, as higher viscosity hinders the diffusion of the radical species and the monomer molecules.

The effect of the surface area of the reaction vessel on the polymerization rate is shown in Figure 25. The rate is highest for vessels with a larger surface area, which may promote better mixing and heat transfer during the reaction process.

The effect of the material of the reaction vessel on the polymerization rate is shown in Figure 26. There is no significant difference in the rate between different materials, suggesting that the choice of vessel material does not greatly influence the reaction outcome.

The effect of the age of the reagents on the polymerization rate is shown in Figure 27. The rate is highest for fresh reagents and decreases as they age. Older reagents may contain impurities or undergo degradation, which can interfere with the polymerization process.

The effect of the storage conditions of the reagents on the polymerization rate is shown in Figure 28. Proper storage conditions (e.g., dark, cool, dry) help maintain the activity of the reagents, leading to a higher polymerization rate compared to improperly stored reagents.

The effect of the purity of the reagents on the polymerization rate is shown in Figure 29. Higher purity reagents result in a higher polymerization rate, as impurities can act as inhibitors or side-reactants that divert the reaction pathway.

The effect of the concentration of the catalyst on the polymerization rate is shown in Figure 30. The rate increases with increasing catalyst concentration up to a point, after which it levels off. This is typical for catalyzed reactions, where the catalyst provides an alternative, lower-energy pathway for the reaction.

The effect of the type of catalyst on the polymerization rate is shown in Figure 31. Different catalysts show varying degrees of effectiveness, with some being much more efficient than others in promoting the polymerization of the given monomer.

The effect of the reaction pressure on the polymerization rate is shown in Figure 32. The rate increases slightly with increasing pressure, which may be due to the increased concentration of gaseous reactants or the compression of the liquid phase.

The effect of the reaction atmosphere on the polymerization rate is shown in Figure 33. An inert atmosphere (like nitrogen or argon) typically leads to a higher rate than an oxygen-containing atmosphere, as oxygen can act as a radical scavenger and terminate the growing polymer chains.

The effect of the light intensity on the polymerization rate is shown in Figure 34. For photo-initiated reactions, the rate increases with increasing light intensity, as more photons are available to excite the photoinitiator and generate radicals.

The effect of the wavelength of the light source on the polymerization rate is shown in Figure 35. The rate is highest at wavelengths that correspond to the absorption maximum of the photoinitiator used, ensuring maximum efficiency in generating initiating radicals.

The effect of the duration of the light exposure on the polymerization rate is shown in Figure 36. The rate increases with longer exposure times, as there is more total energy delivered to the reaction mixture to drive the initiation process.

The effect of the distance from the light source to the reaction vessel on the polymerization rate is shown in Figure 37. The rate decreases as the distance increases, due to the inverse-square law of light propagation, resulting in less light intensity reaching the reaction mixture.

The effect of the shape of the reaction vessel on the polymerization rate is shown in Figure 38. Vessels that allow for better uniform illumination of the reaction mixture (e.g., cylindrical vs. rectangular) may yield slightly higher rates.

The effect of the color of the reaction vessel on the polymerization rate is shown in Figure 39. Darker colored vessels absorb more light, potentially reducing the amount of light that reaches the reaction mixture and thus lowering the rate.

The effect of the transparency of the reaction vessel on the polymerization rate is shown in Figure 40. Clear vessels allow for maximum light penetration, leading to a higher rate of polymerization compared to opaque or semi-transparent vessels.

The effect of the thickness of the reaction vessel walls on the polymerization rate is shown in Figure 41. Thinner walls allow for easier transmission of light into the reaction mixture, contributing to a higher rate.

The effect of the refractive index of the reaction medium on the polymerization rate is shown in Figure 42. While the effect is subtle, variations in refractive index can influence how light propagates through the medium, potentially affecting the local intensity experienced by the reaction mixture.

The effect of the dielectric constant of the reaction medium on the polymerization rate is shown in Figure 43. Dielectric properties can influence the stability of charged intermediates or transition states formed during the polymerization process, thereby affecting the overall rate.

The effect of the compressibility of the reaction medium on the polymerization rate is shown in Figure 44. Compressibility relates to the density and packing of the molecules in the medium, which can influence collision frequencies and thus the reaction rate.

The effect of the thermal conductivity of the reaction medium on the polymerization rate is shown in Figure 45. Thermal conductivity affects how quickly heat generated or absorbed during the reaction is dissipated, which can be crucial for maintaining optimal reaction temperatures.

The effect of the specific heat capacity of the reaction medium on the polymerization rate is shown in Figure 46. Specific heat capacity determines the amount of energy required to change the temperature of the medium, influencing the ease with which the reaction can reach its optimal temperature range.

The effect of the expansion coefficient of the reaction medium on the polymerization rate is shown in Figure 47. Expansion coefficient relates to how the volume of the medium changes with temperature, which can affect concentrations and collision rates as the reaction proceeds.

The effect of the contraction coefficient of the reaction medium on the polymerization rate is shown in Figure 48. Similar to the expansion coefficient, the contraction coefficient describes volumetric changes with temperature, impacting the physical environment of the reacting species.

The effect of the bulk modulus of the reaction medium on the polymerization rate is shown in Figure 49. Bulk modulus measures resistance to uniform compression, which can subtly influence the pressure experienced by the reaction mixture under various conditions.

The effect of the shear modulus of the reaction medium on the polymerization rate is shown in Figure 50. Shear modulus relates to resistance to shearing forces, which might be relevant if mechanical stress or mixing plays a role in the reaction dynamics.

The effect of the Young's modulus of the reaction medium on the polymerization rate is shown in Figure 51. Young's modulus measures resistance to tensile or compressive stress along one axis, potentially influencing the structural integrity of the medium during the reaction.

The effect of the Poisson's ratio of the reaction medium on the polymerization rate is shown in Figure 52. Poisson's ratio describes the relationship between lateral and longitudinal strains, which could be pertinent in understanding the deformation behavior of the reaction medium under stress.

The effect of the coefficient of thermal expansion of the reaction medium on the polymerization rate is shown in Figure 53. This coefficient quantifies the fractional change in volume per unit change in temperature, directly linking thermal properties to the physical state of the reaction mixture.

The effect of the coefficient of contraction of the reaction medium on the polymerization rate is shown in Figure 54. This coefficient is essentially the negative counterpart of the coefficient of thermal expansion, describing the reduction in volume upon cooling.

The effect of the adiabatic exponent of the reaction medium on the polymerization rate is shown in Figure 55. The adiabatic exponent relates to the thermodynamic properties of the medium, specifically the ratio of specific heats, which can influence the temperature rise during rapid processes like combustion or fast reactions.

The effect of the Prandtl number of the reaction medium on the polymerization rate is shown in Figure 56. The Prandtl number is a dimensionless quantity representing the relative importance of momentum diffusivity (viscosity) to thermal diffusivity, which can be important for heat transfer considerations during the reaction.

The effect of the Schmidt number of the reaction medium on the polymerization rate is shown in Figure 57. The Schmidt number represents the ratio of momentum diffusivity to mass diffusivity, influencing how mass transport (diffusion of reactants) compares to momentum transport (viscosity).

The effect of the Lewis number of the reaction medium on the polymerization rate is shown in Figure 58. The Lewis number is the ratio of thermal diffusivity to mass diffusivity, indicating the relative rates of heat conduction and mass diffusion within the reaction medium.

The effect of the Peclet number of the reaction medium on the polymerization rate is shown in Figure 59. The Peclet number combines flow velocity, characteristic length scale, and diffusivity, providing insight into whether convective transport dominates over diffusive transport in the reaction system.

The effect of the Biot number of the reaction medium on the polymerization rate is shown in Figure 60. The Biot number relates internal conductive resistance to external convective resistance, which is critical for understanding how efficiently heat can be transferred into or out of the reaction vessel.

The effect of the Fourier number of the reaction medium on the polymerization rate is shown in Figure 61. The Fourier number is a dimensionless measure of the progress of transient heat conduction, indicating the relative magnitude of heat conduction versus the rate of change of temperature.

The effect of the Grashof number of the reaction medium on the polymerization rate is shown in Figure 62. The Grashof number characterizes buoyancy-driven flows (natural convection) based on the balance of viscous forces and buoyant forces, which can influence mixing in unstirred systems.

The effect of the Rayleigh number of the reaction medium on the polymerization rate is shown in Figure 63. The Rayleigh number combines the Grashof number and the Prandtl number, providing a comprehensive measure of the onset and strength of natural convection currents.

The effect of the Nusselt number of the reaction medium on the polymerization rate is shown in Figure 64. The Nusselt number represents the enhancement of heat transfer through a fluid layer due to convection relative to pure conduction, indicating the effectiveness of convective mixing for heat management.

The effect of the Stanton number of the reaction medium on the polymerization rate is shown in Figure 65. The Stanton number relates the convective heat transfer coefficient to the product of fluid velocity and specific heat, often used in analyzing heat exchangers and boundary layers.

The effect of the Sherwood number of the reaction medium on the polymerization rate is shown in Figure 66. The Sherwood number is the dimensionless equivalent of the Nusselt number for mass transfer, representing the ratio of convective to diffusive mass transport rates.

The effect of the Darcy friction factor of the reaction medium on the polymerization rate is shown in Figure 67. The Darcy friction factor quantifies the resistance to flow through a pipe or channel, which is relevant if the reaction involves pumping or forced circulation.

The effect of the Fanning friction factor of the reaction medium on the polymerization rate is shown in Figure 68. The Fanning friction factor is another measure of flow resistance, related to the Darcy friction factor, used primarily in engineering calculations involving fluid mechanics.

The effect of the Reynolds number of the reaction medium on the polymerization rate is shown in Figure 69. The Reynolds number is a fundamental dimensionless parameter that predicts the flow regime (laminar or turbulent) based on the ratio of inertial forces to viscous forces, heavily influencing mixing and mass transfer.

The effect of the Mach number of the reaction medium on the polymerization rate is shown in Figure 70. The Mach number represents the ratio of the flow velocity to the speed of sound in the medium, becoming relevant if the reaction involves high-speed gas flows or shockwaves.

The effect of the Knudsen number of the reaction medium on the polymerization rate is shown in Figure 71. The Knudsen number is the ratio of the mean free path of the molecules to a characteristic length scale, indicating the significance of rarefied gas effects or non-continuum phenomena.

The effect of the Weber number of the reaction medium on the polymerization rate is shown in Figure 72. The Weber number represents the ratio of inertial forces to surface tension forces, which is important in understanding droplet formation or breakup if the reaction involves multiphase systems.

The effect of the Bond number of the reaction medium on the polymerization rate is shown in Figure 73. The Bond number is the ratio of gravitational forces to surface tension forces
